

Overview of Computer Graphics

- What is Computer Graphics?
- Developmental History
- Applications Areas
- Basic Graphics System
- Elements of Image Formation
 - Objects
 - Viewer/Camera
 - Light source(s)
- Color Models

What is Computer Graphics?

- Creation, Manipulation, and Storage of geometric objects (modeling) and their images (rendering) with a computer
- Display those images on screens or hardcopy devices (animation...)
- Other:
 - Image processing, Computer Vision,
 - CAD, GUI
 - Haptics, Virtual Reality,...

What is Computer Graphics?

- Example
 - Where did this image come from?
 - What hardware/software did we need to produce it?

Answer

- Application: The object is an artist's rendition of the sun for an animation to be shown in a domed environment (planetarium)
- Software: Maya for modeling and rendering but Maya is built on top of OpenGL
- Hardware: PC with graphics card for modeling and rendering

Developmental History

- 1885 - CRT (Cathode Ray Tube)
- 1887 - Edison patents motion picture camera
- 1888 - Edison and Dickson record motion picture photos on a wax cylinder

- 1926 – J.L. Baird invents the television (30 line vertical, black and red scan).

Developmental History

- 1967 - GE introduces first full colour real time flight simulator for NASA
- 1974 - Intel develop the 8080 processor.

- 1975
 - Mandelbrot plots fractals
 - Bill Gates starts Microsoft

- 1976 - Steve Jobs and Steve Wozniak start Apple.

Developmental History

- 1977
 - Academy of Motion Pictures Art and Sciences introduces Visual Effects category for Oscars.
 - Star Wars wins oscar for special effects.

- 1978 - Superman wins oscar for special effects.

Developmental History

- 1981
 - IBM introduces the first IBM PC (16 bit 8088 chip)
 - Raiders of the Lost Ark wins an oscar for visual effects.

- 1982 - The Genesis Effect (ILM) for Startrek II is the first all computer animated visual effects shot for film.

Developmental History

- 1983 - First Coke Polar Bears Commercial
- 1984 - PIXAR Opens

- 1985 -The Last Starfighter is the first live action feature film with realistic computer animation of highly detailed models.

Developmental History

- 1995 - Toy Story becomes the first fully 3D computer animation feature film.

- 1996 - Independence Day wins oscar for visual effects.

- 1997
 - Titanic wins oscar for visual effects.
 - PIXAR wins oscar for best short film: Geri's Game.

Developmental History

- 1999
 - The Matrix
 - Disney's Tarzan
 - Star Wars: The Phantom Menace

- 2000
 - Sony Playstation II
 - Walking with Dinosaurs
 - Disney's Shrek

Developmental History: 1950-1960

- Computer graphics goes back to the earliest days of computing
 - Strip charts
 - Pen plotters(e.g. HP 7470)
 - Simple displays using A/D converters to go from computer to calligraphic CRT
- Cost of refresh for CRT too high
 - Computers slow, expensive, unreliable

Developmental History: 1960-1970

- Sketchpad: Ivan Sutherland's PhD thesis at MIT
 - Recognized the potential of man-machine interaction
 - Loop:
 - Display something
 - User moves light pen
 - Computer generates new display
 - Sutherland also created many of the now common algorithms for computer graphics

- Display Processors:

- Rather than have the host computer try to refresh display use a special purpose computer called a display processor unit (DPU)
- Graphics stored in display list (display file) on display processor
- Host compiles display list and sends to DPU

Developmental History: 1960-1970

- Vector graphics:
 - are defined in terms of 2D points, which are connected by lines and curves to form polygons and other shapes
 - each of these points has a definite position on the x- and y-axis of the work plane and determines the direction of the path
 - each path may have various properties including values for stroke color, shape, curve, thickness, and fill.

Developmental History: 1960-1970

Wireframe

Skeletal model

Muscle model

Skin

Hair

Render and Touch up

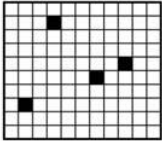

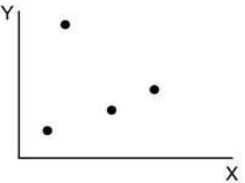

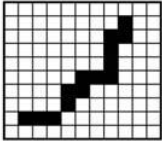

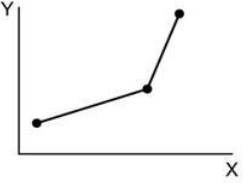

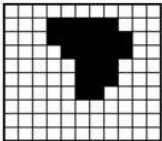

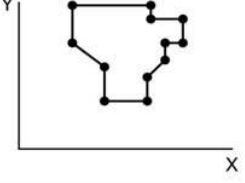

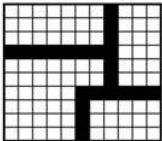

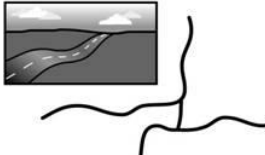

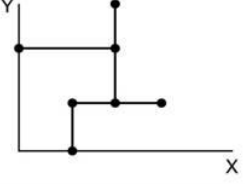

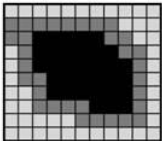

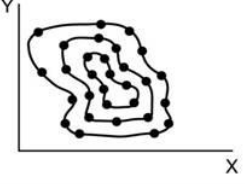

Vector graphics= geometrical model + rendering

Developmental History: 1970-1980

- Raster Graphics:
 - Image produced as an array of picture elements (pixels) in the frame buffer
 - scan lines/area to filled polygons

- Raster vs Vector:

The raster view of the world	Happy Valley spatial entities	The vector view of the world
	 x Points: hotels	
	 Lines: ski lifts	
	 Areas: forest	
	 Network: roads	
	 Surface: elevation	

Developmental History: 1980-1990

- Realism comes to computer graphics

Shading ⇒

flat

smooth

environment

bump

⇐ **Mapping**

Developmental History: 1980-1990

- Special purpose hardware
 - Silicon Graphics geometry engine
 - VLSI implementation of graphics pipeline
- Industry-based standards
 - PHIGS
 - RenderMan
- Networked graphics: X Window System
- Human-Computer Interface (HCI)

Developmental History: 1990-2000

- Completely computer-generated feature-length movies (Toy Story) are successful
- OpenGL API
- DirectX (September 1995 as the Windows Games SDK)
- New hardware capabilities
 - Texture mapping
 - Blending
 - Accumulation, stencil buffers

Developmental History: 2000-...

- Photorealism (real-time)
- Graphics cards for PCs dominate market
 - Nvidia, ATI
- Game boxes and game players determine direction of market
- Computer graphics routine in movie industry: Maya, Lightwave
- Programmable pipelines

Applications Areas

- Look at 5 areas
 - Hardware
 - Rendering
 - Interaction
 - Modeling
 - Scientific Visualization

Game/Film Industry

Computer Aided Design

Medical Imaging

Scientific Visualization

Basic Graphics System

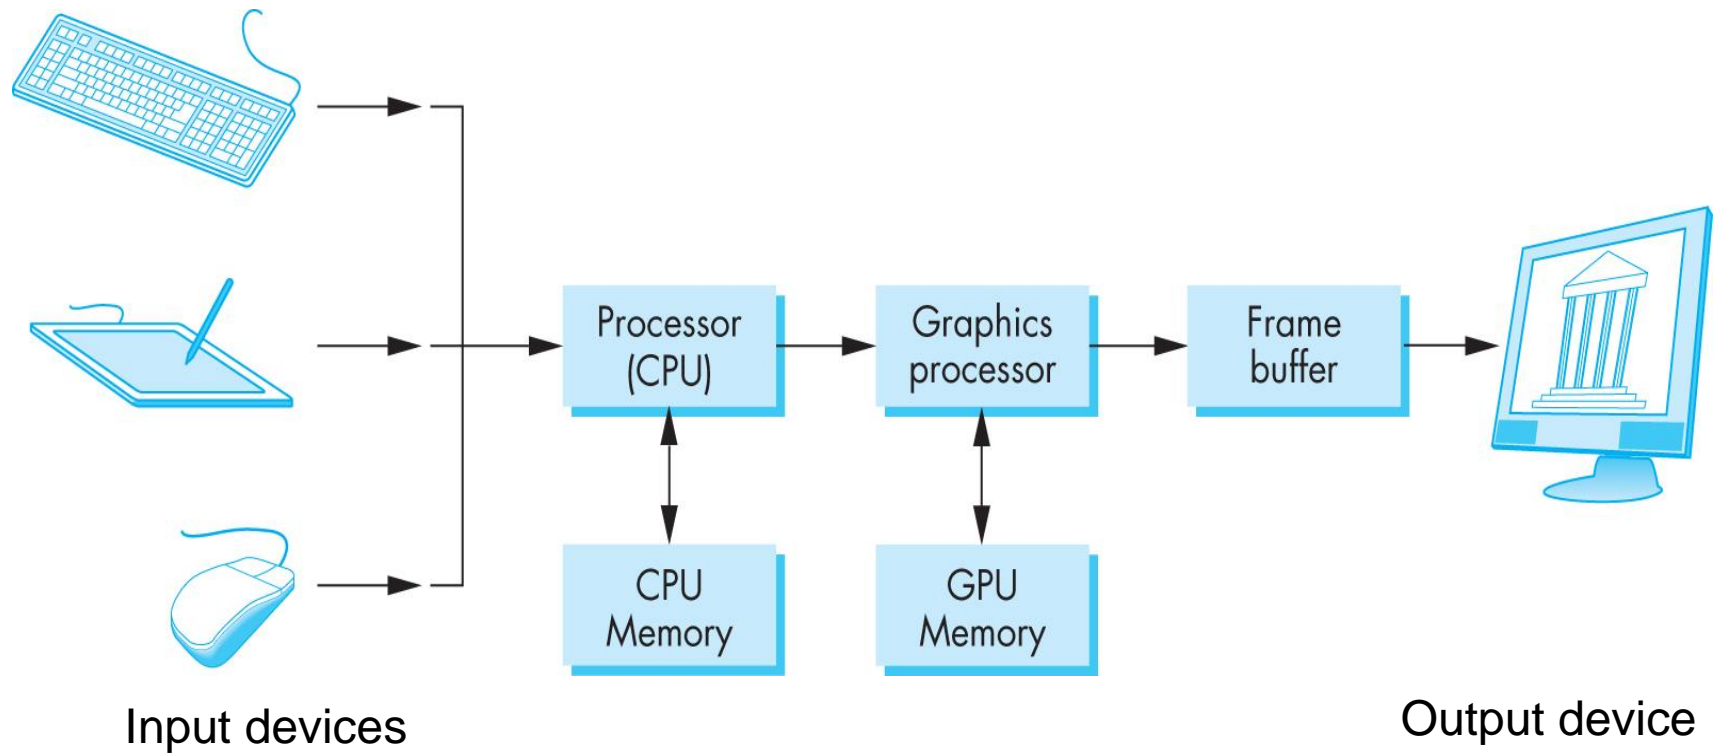

Image formed in frame buffer

CRTs (Cathode Ray Tube Displays)

Can be used either as a line-drawing device (calligraphic) or to display contents of frame buffer (raster mode)

CRTs

CRTs

- Resolution:
 - TV: 640x480x8b 1/4 MB
 - Laserprinter:
 - 300 dpi (8.5"x300)(11"x300) 1.05 MB
 - 2400 dpi (8.5"x2400)(11"x2400) ~64 MB
- Aspect Ratio
 - Frame aspect ratio (FAR) = horizontal/vertical size
- Refresh Rates
- Coordinate system

Basic Graphics System

CRTs

Advantages:

- High resolution possible
- Full color (large modulation depth of E-beam)
- Saturated and natural colors
- Inexpensive, matured technology
- Wide angle, high contrast and brightness

Disadvantages:

- Large and heavy (typ. 70x70cm, 15kg)
- High power consumption (typ. 140W)
- Harmful DC and AC electric and magnetic fields
- Flickering at 50-80 Hz (no memory effect)
- Geometrical errors at edges

LCDs (Liquid Crystal Displays)

- A transmissive technology
- Works by letting varying amounts of a fixed-intensity white backlight through an active filter
- Organic crystals that align themselves together
- When external force is applied they realign themselves
- This is used to change polarisation and filter light

Basic Graphics System

LCDs

Advantages:

- Small footprint (approx 1/6 of CRT)
- Low power consumption (1/4 of CRT)
- Completely flat screen – no geometrical errors
- Crisp pictures - digital and uniform colors
- No electromagnetic emission
- Fully digital signal processing possible
- Large screens (>20 inch) on desktops

Disadvantages:

- High price (presently 3x CRT)
- Poor viewing angle (typ. +/- 50 degrees)
- Low contrast and luminance (typ. 1:100)
- Low luminance (typ. 200 cd/m²)

Frame Buffer (Video RAM)

- Frame buffer
 - size,
 - x, y,
 - pixel depth.
- Resolution
 - Ex: 1024x1024 pixels.
- Bit Planes / Bit Depth
 - ? bit/pixel.
 - color resolution of video RAM.

1 bit/pixel \Rightarrow Monochrome display
8 bits/pixel \Rightarrow 256 màu
24 bits/pixel \Rightarrow 16,777,216 màu

Elements of Image Formation

- Each light ray may have interactions with objects before being absorbed or going to infinity
- One way to form an image is to follow light rays from a point source, finding which rays enter the lens of the camera.

Elements of Image Formation

- In computer, 2D images are formed from a process analogous to how images are formed by physical imaging systems
- Elements of Image Formation:
 - Objects
 - Viewer
 - Light source(s)
 - Light: Global >< Local
 - Cannot compute color or shade of each object independently
 - Some objects are blocked from light
 - Light can reflect from object to object
 - Some objects might be translucent.

Elements of Image Formation

Synthetic Camera Model

Elements of Image Formation

Synthetic Camera Model

- Advantages
 - Separation of objects, viewer, light sources
 - 2D graphics is a special case of 3D graphics
 - Leads to simple software API
 - Specify objects, lights, camera, attributes
 - Let implementation determine image
 - Leads to fast hardware implementation

Colors

- Color: a narrow frequency band within the electromagnetic spectrum, with wavelengths in the range of about 350-750 nm
- In visible band, each frequency corresponds to a distinct color
- High-frequency (short wavelength) appear as Violet, Low-frequency (long wavelength) as Red.

Color Terminology

- **Hue** (color) is a dominated wavelength or pure color with no black or white added (blue, green, red, etc.). The same colors may increase the intensity, but will not change the hue.
- **Saturation** (purity) refers to how strong or weak a color is, depends on the amount of white/black which is added to a color.
e.g: Red and Pink have the same hue, but a different saturation
- **Lightness** is luminance (reflecting objects)
- **Brightness** is luminance (self-luminous objects, e.g: Sun, CRT)
- **Value** (Intensity, Lightness, Brightness) refers to how light or dark a color is (light having a high value).

Color Terminology

- **Tint** is created by adding white to a hue, making it lighter than the original color \Rightarrow Saturation reduced
- **Shade** is created by adding black to a hue, making it darker than the original color \Rightarrow Lightness reduced
- **Tone** is created by adding both white and black to a hue, making it darker/lighter than the original color.

- Gray = Black + White
- Tint, Shade, Tone
 \Rightarrow create different colors of the same hue.

Colors of an object

- Light source emits “white light” (all frequencies of light)
- Object reflects/absorbs some frequencies
- Colors of an object = combination of frequencies reflected

Luminance and Color Images

- Luminance Image
 - Monochromatic
 - Values are gray levels
 - Analogous to working with black and white film/television
- Color Image
 - Has perceptual attributes of Hue, Saturation & Lightness

Do we have to match every frequency in visible spectrum?

⇒ **No!** - Graphic packages provide color palettes to users
(often employ two or more color models)

- **Color model**: an orderly system for creating a whole range of colors from a small set of primary colors.
- **CIE color model**: the most common color space were created by the International Commission on Illumination in 1931, known as the Commission Internationale de l'Elclairage (CIE).
 - three primary colors (saturated): X, Y, and Z
 - any color (color gamut): $C = AX + BY + CZ$,
 - normalized: $x = A/(A+B+C)$; $y = B/(A+B+C)$; $z = 1-x-y$

$$\Rightarrow \mathbf{c} = xX + yY + zZ,$$

$$\text{total light intensity: } x + y + z = 1$$

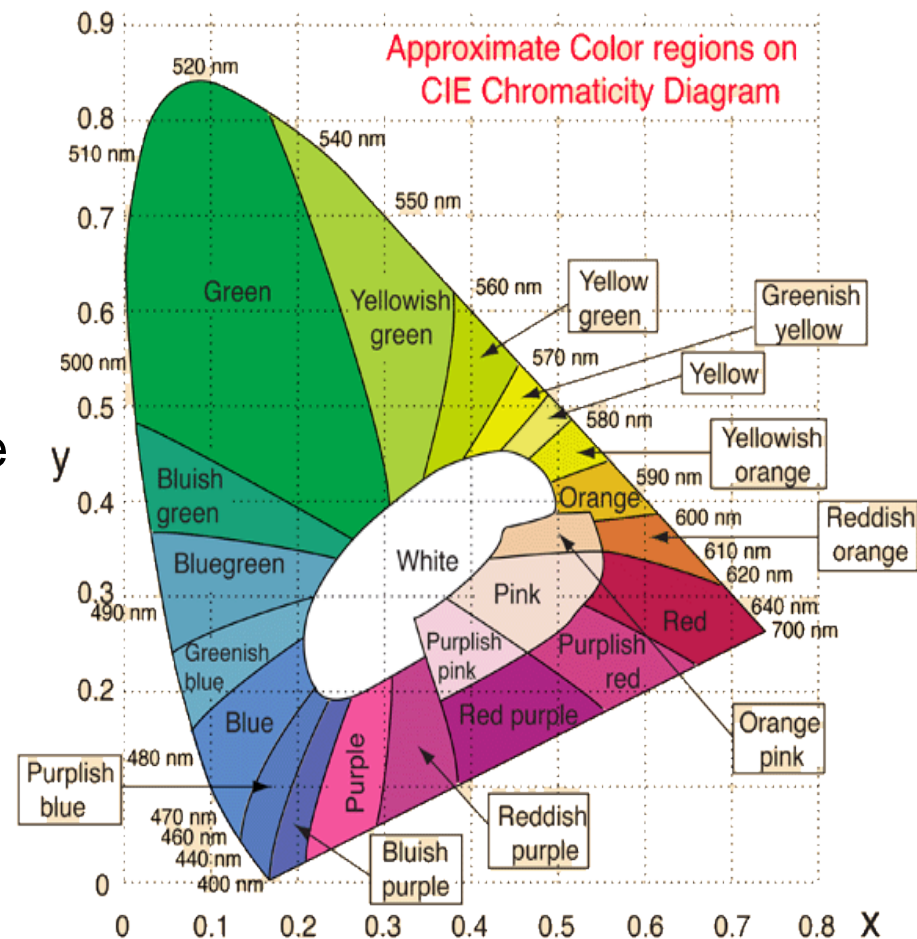

$\Rightarrow \mathbf{c}$ lies in the 3D plane:

$$x + y + z = 1$$

- **CIE chromaticity diagram:**

- Plotting $\mathbf{c}(\lambda) = (x(\lambda), y(\lambda))$ by viewing the 3D curve in an orthographic projection, looking along the z-axis
- **Hue:** inscribing a line from White through the color to the edge of the diagram, Hue is the wavelength of the color at the intersection of the edge and the line.
- **Saturation:** the ratio of the distance of the color from White on the above line and the length of the whole line.

- **CIE chromaticity diagram:**

- Any two colors on a line passing through White and added up to be white are *complementary colors*.
 - e.g: e and f
 - Red \Leftrightarrow Cyan; Green \Leftrightarrow Magenta; Blue \Leftrightarrow Yellow
- Any color within a triangle can be generated by the three vertices of the triangle, called the *color gamut*.
 - a point inside $\triangle IJK$ is a convex combination of 3 points I, J, K

- Color gamut is a subset of all visible chromaticities, so color model does not contain all visible colors
- In the 3D color coordinate system, a subset can contain all colors within a gamut
- Example: RGB color model
 - 3D Cartesian coordinate system
 - Unit cube subset
 - Use CIE XYZ space to convert to

There are two types:

- **Hardware-oriented models:**
 - not intuitive, do not relate to concepts of Hue, Saturation, Brightness
 - RGB \Rightarrow for color monitors
 - CMY (cyan, magenta, yellow), CMYK (cyan, magenta, yellow, black) \Rightarrow for color printing
- **User-oriented models:**
 - HSV (hue, saturation, value), also called HSB (B-brightness)
 - HLS (hue, lightness, saturation)

The RGB Color Model

- **RGB (Red-Green-Blue)**: an additive color model for computer displays uses light to display color.
- **Gamut**: individual contributions of each primary color added together. Gray levels on main diagonal.
 - $C = rR + gG + bB$, where $r, g, b \in [0, 1]$
 - Grays = (x, x, x) , where $x \in (0, 1)$
- **Hue** is defined by the one or t
- **Saturation** can be controlled by varying values of R, G, B
- **Luminance** can be controlled by varying magnitudes while keeping ratios constant

The RGB Color Model

- Conversion from one RGB gamut to another: convert one to XYZ, then convert from XYZ to another
- Form of each transformation:

$$\begin{bmatrix} X \\ Y \\ Z \end{bmatrix} = \begin{bmatrix} X_r & X_g & X_b \\ Y_r & Y_g & Y_b \\ Z_r & Z_g & Z_b \end{bmatrix} \begin{bmatrix} R \\ G \\ B \end{bmatrix}$$

- Where X_r , X_g , and X_b are weights applied to monitor's RGB colors to find X , etc.

Additive vs. Subtractive Color Systems

Magenta

- Print systems use subtractive color system:

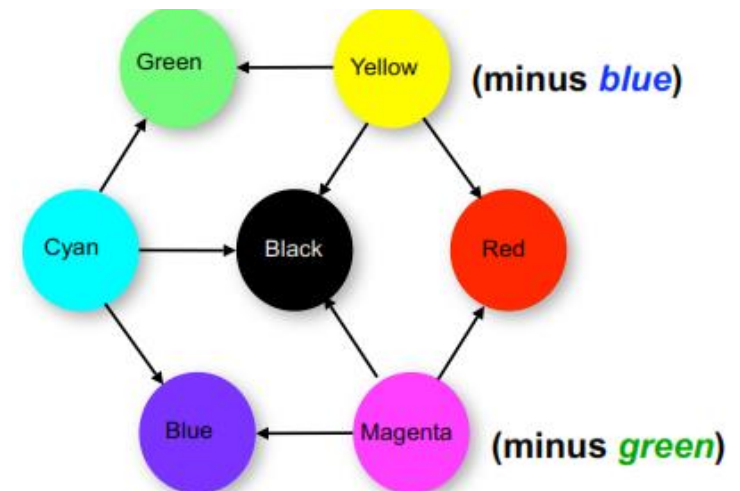

The CMY Color Model

- **CMY** (Cyan-Magenta-Yellow):
the subtractive color model used in light absorbing devices, color printing.
- Complements of RGB:
 - Color specified by what is subtracted from white light
 - C absorbs R, M absorbs G, and Y absorbs B
- Conversion from RGB to CMY

$$\begin{bmatrix} C \\ M \\ Y \end{bmatrix} = \begin{bmatrix} 1 \\ 1 \\ 1 \end{bmatrix} - \begin{bmatrix} R \\ G \\ B \end{bmatrix} \quad (\text{minus red})$$

The HSV Color Model

- HSV: Hue, Saturation, Value (Brightness)
- Hexcone subnet of Cylinder coordinate system
 - The $V = 1$ plane (hexagon) is obtained from the color cube in isometric projection.
 - **Gamut** = (h, s, v) , where $h \in [0, 360)$ and $s, v \in [0, 1]$
 - hue: angle round the hexagon
 - saturation: distance from the center
 - value: axis through the center

The HSV Color Model

- Human eyes can distinguish: 128 hues, 130 saturations/tints, 23 shades of yellow colors, 16 of blue colors
 - $\Rightarrow 128 \times 130 \times 23 = 82720$ colors
- Has intuitive appeal of the artist's tint, shade, and tone model
 - Pure pigments are $(x, 1, 1)$;
 - e.g: pure red $\Leftrightarrow H = 0, S = 1, V = 1$;
 - tints: adding white pigment
 - \Leftrightarrow decreasing S at constant V
 - shades: adding black pigment
 - \Leftrightarrow decreasing V at constant S
 - tones: decreasing S and V

The HLS Color Model

- HLS: Hue, Lightness, and Saturation
- Double-hexcone subnet of Cylinder coordinate system
 - Base is from the hexagon as in HS
 - **Gamut** = (h, l, s) ,
where $h \in [0, 360)$ and $l, s \in [0, 1]$
 - hue: angle round the base
 - lightness: axis through the center
 - saturation: distance from the center
